Question	10
Answer	11

Problem 1

Question

Demonstrate that you know how to use “curl” well enough to correctly POST data to a form. Show that the HTML response that is returned is “correct”. That is, the server should take the arguments you POSTed and build a response accordingly. Save the HTML response to a file and then view that file in a browser and take a screen shot.

Answer

The *cURL* command is a handy command-line utility for making HTTP requests. Using *curl* to stream data, it can be a very useful troubleshooting tool. It also allows us to assess “raw” streaming performance. The following command (*See Figure: 1*) will get the content of the URL and display it in the terminal.

Make requests with data:

I have created a simple php page *curl_posted.php*, which accepts two arguments:

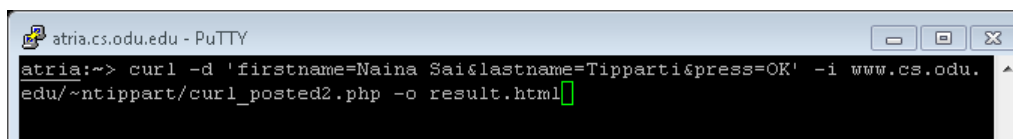

Figure 1: Screen shot of using curl Command

If there’s a “normal” post, use -d to post. -d takes a full “post string”, which is in the format[1]

$\langle \text{variable1} \rangle = \langle \text{data1} \rangle \ \& \ \langle \text{variable2} \rangle = \langle \text{data2} \rangle \ \& \dots$

The “variable” names are the “names” set with “firstname=” in the $\langle \text{input} \rangle$ tags, and the data is the contents you want to fill in for the inputs. The data **must** be properly URL encoded.[1]

We can save the result of the curl command to a file by using -o/-O options.[1]

- -o (lowercase o): result will be saved in the filename provided in the command line
- -O (uppercase O): filename in the URL will be taken and it will be used as the filename to store the result

To store the output in a file (*See Figure: 5*), redirect it as shown above. This will also display some additional download statistics (*See Figure: 4*)[1].

```
1 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
2   "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
3 <html xmlns="http://www.w3.org/1999/xhtml"><head>
4   4 <meta http-equiv="Content-Type" content="text/html;
5     charset=utf-8" />
6 <title>CS532 Web Science | Assignment 1</title>
7 </head>
8 <body>
9 <body>
10 <form method="POST" action="curl_posted2.php">
11   First name: <input type="text" name="firstname"><br>
12   Last name: <input type="text" name="lastname"><br>
13   <input type="submit" name="press" value="OK">
14 </form>
15 </body>
16 </html>
```

curl_posted.php

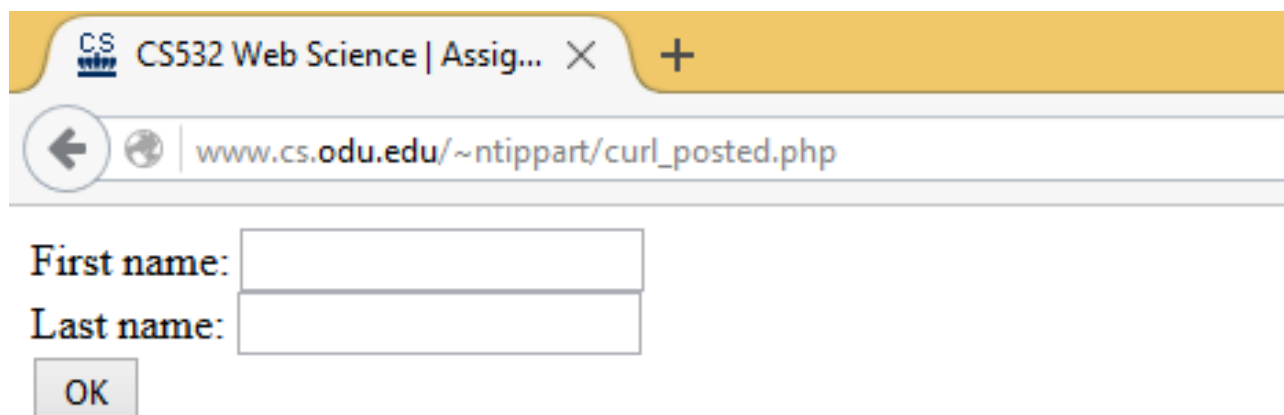

Figure 2: Screen shot of *curl_posted.php* page

Following php script is executed at the server side, when the form is submitted:

```
1 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
2 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
3 <html xmlns="http://www.w3.org/1999/xhtml">
4 <head>
5 <meta http-equiv="Content-Type" content="text/html;
6   charset=utf-8" />
7 <title>CS532 Web Science | Assignment 1</title>
8 </head>
9 <body>
10 <?php
11     $firstname = $_POST['firstname'];
12     $lastname = $_POST['lastname'];
13     echo '\n<h2> Your Full Name is ' . " " . $firstname . "
14     " . $lastname . " " . ' </h2>';
15 ?>
16 </body>
17 </html>
```

curl_posted2.php

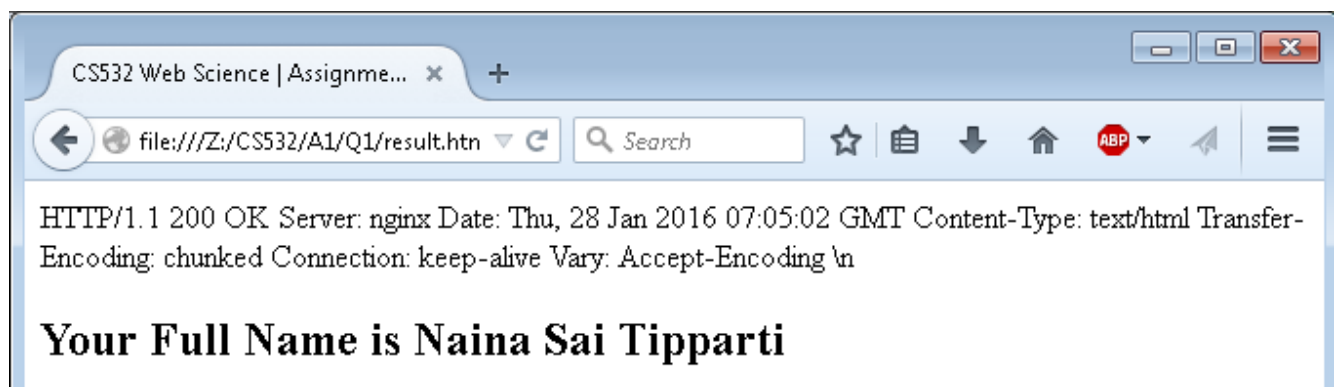

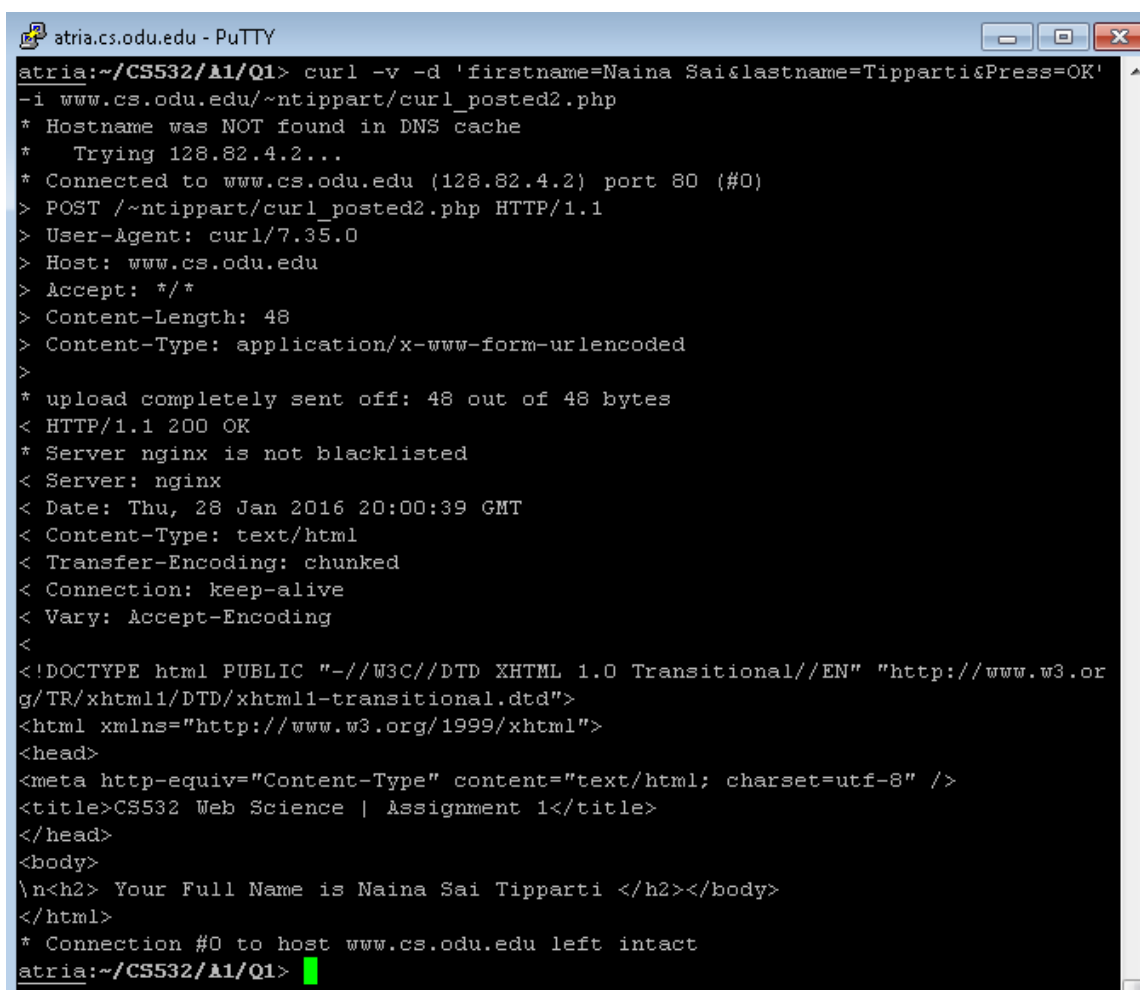

Figure 3: Screen shot of saved HTML response

If curl fails where it isn't supposed to, if the servers don't let you in, if you can't understand the responses: use the `-v` flag (*See Figure: 3*) to get verbose fetching. Curl will output lots of info and what it sends and receives in order to let the user see all client-server interaction (but it won't show you the actual data).[1]

Problem 2

Question

Write a Python program that:

1. takes as a command line argument a web page
2. extracts all the links from the page
3. lists all the links that result in PDF files, and prints out the bytes for each of the links. (note: be sure to follow all the redirects until the link terminates with a "200 OK".)
4. show that the program works on 3 different URIs, one of which needs to be:
`http://www.cs.odu.edu/~mln/teaching/cs532-s16/test/pdfs.html`

Answer

In this python program, modules that are being used:

1. BeautifulSoup is an HTML/XML parser for Python that can turn even invalid markup into a parse tree. It provides simple, idiomatic ways of navigating, searching, and modifying the parse tree.[2]
2. Validators can be any callable that takes a single parameter which checks the new value before it is assigned to the attribute. Validators are permitted to modify a received value so that it is appropriate for the attribute definition. For example, using int as a validator will cast a correctly formatted string to a number, or raise an exception if it can not. However, the correct way to use a validator that ensure the correct type is to use the Type validator.[3]
3. Requests takes all of the work out of Python HTTP/1.1 making your integration with web services seamless. Theres no need to manually add query strings to your URLs, or to form-encode your POST data. Keep-alive and HTTP connection pooling are 100% automatic, powered by urllib3, which is embedded within Requests.[4]

70         sys.exit(1)
71     main(sys.argv[1])
72     sys.exit(0)
```

Problem 3

Question

Consider the "bow-tie" graph in the Broder et al. paper (fig 9):

<http://www9.org/w9cdrom/160/160.html>

Now consider the following graph:

A → B
B → C
C → D
C → A
C → G
E → F
G → C
G → H
I → H
I → J
I → K
J → D
L → D
M → A
M → N
N → D
O → A
P → G

For the above graph, give the values for:

IN:

SCC:

OUT:

Tendrils:

Tubes:

Disconnected:

Answer

Figure 9: Drawing of example graph

Figure 9: is a “bowtie” [5] graph of the included points, generated using Graphviz [6].

IN: {M,O,P}	“Connects into SCC, but not out from SCC”
SCC: {A,B,C,G}	“SCC – all contained nodes are interconnected”
OUT: {D,H}	“Connects out from SCC, but not in to SCC”
Tendrils: {I,J,K,L}	“In or out excluding all SCC”
Tubes: {N}	“IN \rightarrow OUT or OUT \rightarrow IN connection”

Disconnected:{E,F} “Not connected to other sites”

The descriptions of each node is a matter of interpretation. Explanations have been provided

for each value assignment.

IN: M, O, P

The IN components form the starting point for connection to the SCC[7]. They all sit at the start of the graph. In this graph, because of how the SCC and tubes are defined, the only IN components are M, O, P .

SCC: A, B, C, G

The Strongly Connected Component consists of those heavily linked items connected to from the list of nodes listed as part of IN[7]. It’s an A, B, C, G world.

OUT: D, H

The OUT components exit the SCC, but do not link back to it[7]. The only members of OUT are D, H , who forms a sink from members of the SCC and the tendrils.

Tendrils: I, J, K, L

The *Tendrils* are pages that cannot reach the SCC or are not reached from the SCC[7]. The tendrils come from other graphs and only join the whole via *DorH*.

Tubes: N

Then there are *tubes*, which pass from IN to OUT without going through SCC[7]. N is a tube linking from M (from IN) to *DorH* (from OUT).

Disconnected: E, F

The Disconnected components link to no one in the graph, and stand alone. They are not defined explicitly by Broder, et. al, but their meaning is implied within the paper.
